# From Prompt to Praxis: A Contract-First Orchestration Framework for AI-Powered Game Asset Authoring

## Foundational Infrastructure for AI Discovery and Navigation

The central research objective is to develop a robust, Rust-based `CHAT_DIRECTOR` capable of transforming AI-Chat from an ad-hoc code generator into a disciplined agent operating within a well-defined, machine-readable ecosystem . This requires establishing a foundational infrastructure that prioritizes discovery and navigation before any code generation occurs. The core strategy is to replace ambiguous prompt instructions with verifiable contracts and provide the AI with a comprehensive, real-time map of its operational environment . This approach directly addresses critical challenges inherent in large-scale, collaborative content creation, such as schema drift, inconsistent quality, and context drift [1] [19] [64]. By grounding all actions in a single source of truth, the system ensures that every artifact generated by the AI adheres to the established architectural and tonal constraints of the Horror$Place constellation. The foundational infrastructure is built upon four pillars: the Capability Catalog, which serves as a dynamic map of the entire ecosystem; Manifest-Driven Routing, which provides navigational guidance for artifact placement; Spine-Aware Indexing, which offers deep schema-level knowledge; and a dual-use architecture that enables this infrastructure to function as both a powerful local tool and an embeddable service. Together, these components create a contract-first orchestration layer that guides the AI through a structured workflow, ensuring compliance, consistency, and efficiency.

The cornerstone of this discovery-first approach is the Capability Catalog, a dynamic, machine-readable document that synthesizes information from multiple sources into a single, coherent view of the Horror$Place universe . This catalog is not merely a static list but a comprehensive summary of the constellation's rules and capabilities, accessible programmatically by the AI-Chat . The design, detailed in the provided materials, specifies a stable JSON schema for this catalog, ensuring that any integration can rely on a consistent format for all discovery-related data . The Rust implementation involves creating a `CapabilityCatalog` struct that mirrors this schema and populating it from

the loaded SchemaSpine and RepoManifests . Functions like `ChatDirector::catalog()` serve as the primary entry point, accepting optional filters (e.g., by object kind, tier, or phase) to provide targeted information, while the `hpc-chat-director describe` CLI command exposes this functionality to local scripts and CI pipelines . For example, when an AI needs to know what is allowed in Tier 1, it can query the catalog to get precise details about permitted `objectKinds`, their associated schemas, required invariants and metrics, and the specific policies governing the target repositories . This eliminates guesswork and reduces the cognitive load on the AI, allowing it to focus on creative tasks rather than administrative ones. The use of Rust's `serde` library for serialization makes this implementation idiomatic and efficient, leveraging Rust's strengths in performance and memory safety [52] [123].

Complementing the static data of the catalog is the ManifestIndex, which provides dynamic, context-aware guidance for path planning and artifact routing . While the catalog tells the AI *what* it can create, the manifest index tells it *where* to create it. This is achieved through functions like `ManifestIndex::explain_route()`, which takes an `object_kind` and `tier` as input and returns a `RouteExplanation` containing the target repository, the calculated file path, and any applicable policies or authoring hints . This mechanism prevents common errors such as placing a public asset in a private repository or violating tier-specific rules, such as writing raw narrative fields to a Tier 1 repository . The `authoringHints` field adds a crucial layer of human wisdom, explaining the rationale behind certain rules (e.g., "Tier 1 rejects raw narrative fields; contracts only"), which helps the AI understand the 'why' behind the 'what' . This creates a robust system for guiding artifacts through the correct development pipeline, which typically follows a progression from Schema to Registry, Bundles, LuaPolicy, and finally Adapters . The implementation leverages Rust's strong type system to model these concepts clearly, ensuring that the logic for interpreting `repo-manifest.hpc.*.json` files is encapsulated and reliable . The manifest index thus acts as a sophisticated router, translating high-level AI intents into concrete, compliant filesystem destinations.

The third pillar of the foundational infrastructure is the SpineIndex, which provides deep, schema-aware knowledge for generating structurally sound contracts . This module goes beyond simple metadata to offer detailed profiles of each `objectKind`, accessible via functions like `SpineIndex::describe_object_kind()` . These profiles include a complete list of required and optional fields, the specific invariants and entertainment metrics that apply to the object kind, and its allowed phases and tiers . More importantly, the spine index provides `safe_defaults`, which are guaranteed-valid ranges for invariants and metrics derived directly from the spine's JSON definitions . This is a critical feature for scaffolding, as it allows the AI to start with a valid payload and fill in the creative details, rather than inventing values from scratch which often leads to out-of-

bounds errors [63]. The spine index also computes derived metrics based on interaction rules and known values, further enriching the context available to the AI . This deep integration with the schema spine ensures that all generated content begins its life within the defined boundaries of the Horror$Place universe, drastically reducing the risk of schema drift and ensuring that all artifacts are inherently compliant with the base specification [21]. The Rust implementation treats the spine as a first-class citizen, loading and parsing the various spine JSON files (`schema-spine-index-v1.json`, `invariants-spine.v1.json`, etc.) at startup and building an in-memory index that can be queried efficiently .

Finally, the entire discovery and navigation framework is built on a dual-use architecture, designed to function seamlessly in both offline/local environments and embedded/runtime/editor environments . For local use, the primary interface is the `hpc-chat-director` command-line interface (CLI). This self-contained binary, compiled from Rust, can be run anywhere without complex setup, making it ideal for pre-commit hooks, CI/CD pipelines, and local authoring sessions [32]. The CLI exposes a set of subcommands —`describe`, `plan`, `skeleton`, `validate-response`, and `apply`—that correspond directly to the core Rust APIs, providing a complete, offline toolchain for AI-powered authoring . For embedded use, the same core logic is exposed through a thin HTTP service layer . The `http::serve()` function starts a web server that exposes the exact same endpoints as the CLI commands, using the same stable JSON schemas for requests and responses [75][107]. This allows IDE plugins, editor extensions, or other services to interact with `CHAT_DIRECTOR` over a network connection, removing the overhead of starting a new process for every API call and enabling high-frequency, interactive workflows [30][112]. This separation of core logic from transport mechanism is a hallmark of modern developer tooling and ensures that the powerful discovery and navigation capabilities are accessible to the widest possible range of users and integrations. The configuration system, managed by the `Config` module, supports different execution modes (`Local`, `CI`, `EditorPlugin`) and AI modes (`StrictSchema`, `Suggestive`, `Learning`), allowing the behavior of `CHAT_DIRECTOR` to be adapted to the specific context in which it is running .

| Component | Key Rust Functions | Primary Purpose | Interface(s) |
| --- | --- | --- | --- |
| **Capability Catalog** | `ChatDirector::catalog()`, `cli_describe.rs` | Provides a centralized, machine-readable map of all capabilities, rules, and policies in the constellation. | CLI (`describe`), Library API |
| **Manifest Index** | `ManifestIndex::explain_route()`, `ManifestIndex::route()` | Dynamically determines the correct repository and path for an artifact based on its `objectKind` and `tier`. | Library API |
| **Spine Index** | `SpineIndex::describe_object_kind()`, `SpineIndex::safe_defaults()` | Provides deep schema-level information, including field requirements, invariants, and safe default metric values. | Library API |
| **Configuration & Environment** | `Config::from_env()`, `ChatDirector::environment_summary()` | Loads configuration, detects the constellation root, and summarizes the current execution environment. | Library API, CLI |

This integrated foundation transforms `CHAT_DIRECTOR` from a passive validator into an active guide. It equips the AI with the necessary context to make informed decisions, preventing many classes of errors before they occur. By codifying the rules of the Horror$Place universe into discoverable, queryable interfaces, the system lays the groundwork for a more reliable, scalable, and collaborative AI-assisted authoring process.

## Manifest-Driven Routing and Path Planning

Once an AI-Chat agent has been equipped with a high-level understanding of the Horror$Place universe via the Capability Catalog, its next critical task is to translate intent into a concrete plan for artifact creation, which includes determining the correct destination for the generated file. This is the domain of manifest-driven routing and path planning, a crucial component of the `CHAT_DIRECTOR` architecture that bridges the gap between abstract intent and concrete filesystem operations . The system's reliance on `repo-manifest.hpc.*.json` files as the authoritative source of truth for routing policies ensures that all artifacts are placed correctly according to their `objectKind`, `tier`, and other attributes, thereby enforcing organizational integrity and policy compliance [141]. The Rust implementation formalizes this process into a set of robust APIs that provide clear, predictable, and explainable routing decisions, moving beyond simple lookups to offer insightful guidance that can be used by both automated agents and human developers.

The core of the manifest-driven routing system is the `ManifestIndex` module, which is responsible for loading and processing all repository manifests . Upon initialization, it

iterates through the paths resolved by the `Config` module, parses each `repo-manifest.hpc.*.json` file, and constructs an internal index of all available repositories and their rules . Each manifest contains a rich set of metadata, including the repository's `tier`, a list of `allowedObjectKinds`, a `schemaWhitelist` to prevent schema drift, `defaultPaths` templates for generating file paths, and a series of `policies` like `OneFilePerRequest` . The `ManifestIndex` stores this information in a structured format, allowing for efficient querying. The primary function exposed by this module is `ManifestIndex::explain_route()`, which takes an `object_kind` and a `tier` as inputs and returns a `RouteExplanation` . This return value is not just a simple string path; it is a detailed report that includes the name of the target repository, the fully resolved `target_path` based on the default path template, a list of applicable policies, and any `authoringHints` that provide context on why certain rules exist . For instance, if an AI attempts to generate a `moodContract` for `Tier1Public`, calling `explain_route` would confirm its validity, identify the `Horror.Place` repository as the target, and reveal the default path pattern and the policy against using raw narrative fields .

To handle more complex scenarios, the `ManifestIndex` also provides other specialized functions. `ManifestIndex::route()` performs the same core logic as `explain_route` but may return a more minimal result optimized for programmatic use where detailed explanations are not needed . Conversely, `ManifestIndex::quarantine_route()` is designed for handling forbidden combinations, such as when an `object_kind` is not whitelisted for a given `tier` . Instead of simply failing, it might attempt to find a suitable alternative route or return a specific error indicating that the combination is explicitly quarantined, which can be useful for debugging and improving AI prompting. Another important function is `ManifestIndex::min_rwf_for_route()`, which calculates the minimum `Required World Fabrication` (RWF) score required for a given artifact route, helping the AI to understand the resource cost associated with placing an item in a particular repository . These functions work together to create a resilient and informative routing engine that can handle a wide variety of situations, from straightforward placements to complex policy conflicts. The implementation leverages Rust's `Result` type heavily, returning specific `RoutingError` enums (like `RouteNotFound`, `TierViolation`, or `ImplicitDeny`) that carry detailed information about what went wrong, allowing the calling code to provide precise feedback to the AI .

The integration of authoring hints and AI-specific policies into the manifest structure represents a significant enhancement over simpler routing schemes . The `RepoManifest` definition has been extended to include an `authoringHints` array and an optional `aiPolicies` object . `AuthoringHint` objects contain a `ruleId` and a

descriptive `description`, providing the AI with contextual advice. For example, a hint might state `HP-T1-001: Tier 1 rejects raw narrative fields; contracts only` . The `aiPolicies` object can define rules specifically for AI agents, such as maximum file sizes, forbidden fields, or mandatory inclusion of a `deadLedgerRef` for artifacts in certain tiers . The `ManifestIndex` queries these fields and makes them available through `authoring_hints_for_repo()` and `ai_policies_for_repo()` . This allows the AI-Chat to proactively avoid common mistakes. Before generating a file for a Tier 1 repository, it can check the manifest for hints and policies, see that raw narrative is forbidden, and adjust its generation plan accordingly. This proactive avoidance of errors is far more efficient than a reactive validation loop. The `explain_route` function becomes a powerful pre-generation utility, giving the AI a clear mental model of where its creation will land and what rules it must obey .

The table below illustrates how these functions work together in a practical scenario, showing the progression from a high-level request to a concrete, validated routing decision.

| Step | Function / Action | Input | Output / Result | Rationale |
|---|---|---|---|---|
| 1 | AI Intent | "Create a new event for a public dungeon." | `AiAuthoringRequest` with `object_kind=eventContract`, `tier=Tier1Public` | The AI formulates an initial request based on user intent. |
| 2 | Path Planning | `director.plan_paths(request)` | Candidate `(repo, path, tier)` tuples | The `CHAT_DIRECTOR` uses the manifest index to suggest valid paths based on the request. |
| 3 | Detailed Route Explanation | `manifest_index.explain_route(eventContract, Tier1Public)` | `RouteExplanation` object | The system provides a detailed breakdown of the chosen path, including policies and hints. |
| 4 | Policy Check | `manifest_index.validate_target(eventContract, Horror.Place, Tier1Public)` | `Ok(())` | Confirms that the event contract is indeed allowed in the public repository. |
| 5 | Skeleton Generation | `skeleton_generator.for_event(request)` | `AnnotatedSkeleton` with path pre-filled | Generates a valid JSON skeleton with the correct path and annotations for the AI to fill. |
| 6 | Final Validation | `validator.validate_manifests(response, route_explanation)` | `Vec<Diagnostic>` | Ensures the final generated file still conforms to all manifest policies. |

This structured, multi-step process demonstrates how manifest-driven routing is not a single action but a continuous thread woven through the entire authoring workflow. It begins with planning, informs skeleton generation, and culminates in final validation. By embedding this logic deeply within the Rust `CHAT_DIRECTOR`, the system ensures that routing decisions are always based on the latest, authoritative manifest data and are subject to the same rigorous validation as any other part of the system. This approach stands in stark contrast to hardcoding paths or relying on the AI's ability to infer repository structures from names or documentation. It provides a scalable, maintainable, and highly effective solution for navigating the complexity of a multi-repo constellation, ensuring that every piece of generated content finds its way to the correct home.

# Spine-Aware Indexing and Structured Scaffolding

Beyond knowing *where* to place an artifact, the AI-Chat requires a deep understanding of *what* to create. This necessitates a spine-aware indexing system that can provide granular, schema-level guidance, moving the AI from a state of uncertainty to one of confident generation. The `SpineIndex` module, powered by the schema spine, is the linchpin of this capability, offering detailed profiles of every `objectKind` and providing the essential scaffolding needed to generate structurally sound and compliant contracts . The most innovative aspect of this system is its focus on structured scaffolding through the `generate_skeleton` functionality, which provides AI agents with a pre-formatted, annotated blueprint of the desired output, complete with `safe_defaults` and explicit instructions on which fields require creative input . This approach fundamentally changes the AI's role from a free-form text generator to a meticulous scaffold-filler, dramatically reducing the likelihood of structural errors, schema drift, and invalid numeric ranges.

The `SpineIndex` is constructed at the initialization of the `CHAT_DIRECTOR` by loading and parsing several key JSON files, including `schema-spine-index-v1.json`, `invariants-spine.v1.json`, and `entertainment-metrics-spine.v1.json` . These files collectively form the "spine" of the constellation, defining the official vocabulary and rules of the Horror$Place universe. The `SpineIndex` ingests this data, creating in-memory representations of schemas, invariants, and metrics, and linking them together logically . For example, it knows which invariants apply to a `moodContract` versus an `eventContract`. The primary API surface for this module is a set of query functions. `SpineIndex::describe_object_kind(kind)` returns an `ObjectKindProfile`, a detailed record of an object's properties . This profile includes the `schemaRef`, a list of required and optional fields, the `allowedPhases` and `allowedTiers`, and, critically, the lists of `requiredInvariants` and `requiredMetrics` that must be present in any valid instance of that object kind . This allows the AI to programmatically determine the exact shape of the JSON it needs to produce for a given task.

Perhaps the most powerful feature of the spine-aware indexing is the provision of `safe_defaults`. The `SpineIndex::safe_defaults(kind, tier)` function analyzes the spine data, including global ranges and any `tierOverrides`, to compute a set of invariant and metric bands that are guaranteed to be valid for a given `objectKind` and `tier` . For example, when generating a `moodContract` for `Tier1Public`, the AI can call this function and receive back a `DefaultBands` object containing safe, valid ranges for CIC, MDI, AOS, DET, LSG, HVF, SHCI, SPR, UEC, EMD, STCI, CDL, and ARR . This transforms the problem of "generating numbers" into the

much simpler problem of "filling numbers within these predefined, safe ranges." It completely eliminates the risk of the AI hallucinating an intensity band of 12.0 for an DET metric that is capped at 10.0, a common failure mode highlighted in the original research . This concept is further extended by functions like `SpineIndex::template_for_tile_class()`, which can provide even more contextually relevant defaults based on the intended use case of the tile or region . This level of detail ensures that the numerical foundations of the generated content are always grounded in the established horror invariants.

The culmination of the spine-aware indexing capabilities is the `SkeletonGenerator` module, which implements the `generate_skeleton` function . This module consumes the detailed profiles from the `SpineIndex` to produce a complete, syntactically correct, but semantically empty, JSON representation of the requested `objectKind`. However, its true innovation lies in its annotation system. The resulting `AnnotatedSkeleton` is not just a JSON blob; it is a carefully crafted scaffold where each field is tagged with metadata that instructs the AI on how to proceed . The tags include:

- `DoNotModify`: For identity fields like `id` or `schemaRef` that should be left as-is.
- `SafeDefault`: For fields that have sensible defaults provided by the spine and can be accepted as-is or slightly tweaked.
- `AiFill`: For all other fields that require creative input from the AI .

This annotation system provides a clear and unambiguous contract between the `CHAT_DIRECTOR` and the AI-Chat. When presented with a skeleton, the AI understands exactly which parts of the document are its responsibility to fill. This structured scaffolding approach has profound implications for the authoring process. It shifts the burden of structural correctness from the AI, which is notoriously prone to hallucination and inconsistency, to the `CHAT_DIRECTOR`, which is backed by the immutable, authoritative data of the spine. The AI's job becomes one of refinement and creativity within a safe, pre-defined envelope, rather than the difficult task of constructing a valid document from scratch. The `SkeletonGenerator` also includes functions like `with_archetype()` to apply pre-defined archetypes and `validate_against_spine()` to ensure the generated skeleton itself is structurally sound before it is ever shown to the AI . This multi-layered approach, combining deep indexing with structured scaffolding, creates a robust and highly effective system for guiding AI-Chat agents to produce high-quality, compliant assets consistently.

| Feature | Rust Function/API | Description | Impact on AI-Chat |
|---|---|---|---|
| Object Kind Profiling | `SpineIndex::describe_object_kind()` | Returns a detailed profile of an object kind, including required fields, invariants, and metrics. | Eliminates guessing about the shape of a contract. |
| Safe Default Bands | `SpineIndex::safe_defaults()` | Computes guaranteed-valid numeric ranges for invariants and metrics based on the spine and tier. | Prevents out-of-bounds values and ensures numerical compliance from the start. |
| Archetype Application | `SkeletonGenerator::with_archetype()` | Applies a pre-defined archetype to a generated skeleton, setting initial values for key fields. | Provides a quick-start template for common patterns, accelerating generation. |
| Annotation System | `SkeletonGenerator::annotate_fields()` | Tags each field in the skeleton with `AiFill`, `SafeDefault`, or `DoNotModify` instructions. | Gives the AI a clear, unambiguous contract on what it is responsible for creating. |
| Structural Validation | `SkeletonGenerator::validate_against_spine()` | Verifies the generated skeleton against the underlying schema and spine rules. | Ensures the scaffold itself is structurally sound before AI interaction. |

By integrating these capabilities, the `CHAT_DIRECTOR` provides a powerful on-ramp for AI-Chat agents. Instead of facing a blank screen and a vague prompt, the agent is handed a detailed blueprint of the world it is asked to build in. This not only improves the quality and reliability of the output but also makes the authoring process more transparent and controllable, aligning perfectly with the research goal of creating a foundational infrastructure for discoverable and navigable AI interaction.

## Dual-Use Architecture: Offline Tooling and Embedded Services

A fundamental requirement for the `CHAT_DIRECTOR` is its ability to operate effectively across two distinct environments: as a standalone, offline/local tool and as an embeddable service within runtime or editor environments . This dual-use architecture ensures broad accessibility and flexibility, catering to a diverse range of workflows from scripted CI/CD pipelines to interactive IDE integrations. The design achieves this separation by decoupling the core business logic—the discovery, planning, and validation engines—from the transport mechanism, whether it be a command-line interface (CLI) or a HyperText Transfer Protocol (HTTP) server. This modular approach, enabled by Rust's performance, safety, and compilation capabilities, allows the same powerful functionalities to be accessed via different interfaces without duplicating effort or

compromising on either performance or usability [32] [75]. The offline tooling is primarily delivered through a self-contained `hpc-chat-director` CLI binary, while the embedded service mode is provided by a lightweight HTTP server that exposes the same APIs over a network socket .

For offline and local use, the `hpc-chat-director` CLI is the primary vehicle for delivering the `CHAT_DIRECTOR`'s capabilities. Built using Rust, this binary can be statically linked, resulting in a single executable file that bundles the application and all its dependencies, requiring no external installations or complex configurations [32]. This makes it exceptionally easy to distribute and integrate into various local development and automation contexts. The CLI is structured around a set of subcommands that map directly to the core Rust APIs, providing a familiar and powerful interface for developers and automated systems alike . Commands like `init`, `plan`, `describe`, `validate-response`, and `apply` form a complete, linear workflow for AI-assisted authoring . For example, a developer can run `hpc-chat-director describe --json --object-kind moodContract` to get a detailed profile of the `moodContract` object kind, which can then be injected into the AI's prompt. Similarly, a pre-commit hook in a Git repository could execute `hpc-chat-director validate-response --json < generated_file.json` to automatically enforce constellation rules before allowing a commit, catching errors early in the development cycle [9] [27]. The CLI's design, using a framework like `clap` for argument parsing, allows for the creation of intuitive and powerful commands, such as the `describe` subcommand with its flexible filtering options (`--object-kind`, `--phase`, `--tier`, `--repo`) . This offline-first approach ensures that the `CHAT_DIRECTOR` is always available, even without internet access or a running server, making it a reliable partner for any authoring task.

On the other end of the spectrum, the dual-use architecture provides a seamless pathway for integrating `CHAT_DIRECTOR` into runtime and editor environments through a dedicated service mode . This is implemented by adding a new flag, `--serve`, to the main executable. When invoked, this flag triggers the `http::serve()` function, which starts an Axum-based web server [75] [107]. This server exposes a RESTful API with endpoints that mirror the functionality of the CLI commands. For instance, `GET /v1/describe` corresponds to the `describe` command, `POST /v1/plan` takes a prompt and returns an `AiAuthoringRequest`, and `POST /v1/skeleton` generates a skeleton for a given request . Crucially, this HTTP API uses the exact same stable JSON schemas for its requests and responses as the CLI's `--json` output, ensuring a consistent interface regardless of the transport mechanism [123]. This design choice is paramount, as it allows any client, whether it's a custom-built game tool, an IDE extension, or another AI orchestrator, to interact with `CHAT_DIRECTOR` using a standardized, machine-

readable protocol. An editor plugin, for example, could make an HTTP request to `/plan` whenever a user types a new prompt, instantly receiving a structured request object to guide the AI's response, all without the latency of spawning a new process [112].

This dual-use model elegantly solves the trade-offs between local tools and embedded services. The CLI excels in batch processing, scripting, and environments where process isolation is preferred. Its self-contained nature makes it ideal for CI/CD pipelines, where reproducibility and simplicity are key. The service mode, in contrast, excels in interactive, low-latency scenarios typical of an integrated development environment (IDE) or a live editing session. By avoiding the overhead of process startup and teardown for every API call, the HTTP interface enables a fluid, conversational experience between the developer, the AI, and the `CHAT_DIRECTOR`. Furthermore, the architecture is designed with telemetry in mind, featuring a pluggable `TelemetrySink` trait that can be connected to log events from either mode . This allows for the collection of usage data and validation outcomes, which can be invaluable for analyzing common failure modes and driving future improvements to the spine, manifests, and AI-guidance strategies [47]. The configuration system, with its `ContextMode` enum (`Local`, `CI`, `EditorPlugin`), allows the `CHAT_DIRECTOR` to adapt its behavior based on how it was invoked, enabling stricter enforcement in CI and richer suggestions in an editor plugin . This thoughtful design ensures that the `CHAT_DIRECTOR` is not just a piece of software, but a versatile and integral part of the entire authoring ecosystem, serving the needs of both automated systems and interactive developers with equal proficiency.

| Aspect | Offline (CLI) | Embedded (HTTP Service) | Implementation Details |
|---|---|---|---|
| **Primary Use Case** | Scripting, CI/CD, Pre-commit Hooks, Local Development Sessions [9] | Interactive IDE Plugins, Live Editing Tools, Agent Orchestration [1,12] | The CLI is optimized for non-interactive, scriptable workflows, while the HTTP server is optimized for low-latency, interactive queries. |
| **Performance** | Higher latency due to process spawning for each command. | Lower latency as the service remains resident in memory, eliminating process startup overhead [3,4]. | The HTTP server runs as a long-lived process, whereas the CLI spawns a new process for each invocation. |
| **Distribution** | Single, statically-linked binary (`hpc-chat-director`) with no external dependencies [3,2]. | Requires a server to be started and maintained. Can be packaged as a binary with a `--serve` flag. | The CLI's static linking simplifies distribution immensely. The HTTP server can be deployed as a daemon or alongside an application. |
| **Interface** | Command-line arguments and standard input/output streams. | Standardized JSON over HTTP using stable schemas for requests and responses [1,2,3]. | The CLI uses `clap` for parsing. The HTTP server uses `axum` to define routes and serialize/deserialize JSON payloads. |
| **State Management** | Stateless per invocation; relies on command-line flags for configuration. | Stateful; can maintain connections and potentially cache results for subsequent requests. | The CLI is stateless by nature. The HTTP server can implement state management, though the current design keeps it stateless for simplicity. |
| **Integration** | Easy to integrate into shell scripts and build systems. | Requires an HTTP client library. Enables tight integration with web technologies and languages with good HTTP support. | The CLI integrates naturally with any system that can execute a shell command. The HTTP interface can be consumed by virtually any programming language. |

By providing both interfaces, the `CHAT_DIRECTOR` architecture embraces the full spectrum of modern software development practices. It respects the power and simplicity of traditional command-line tools while embracing the flexibility and connectivity of modern web services. This dual-use design is not an afterthought but a core principle of the system's architecture, ensuring its capabilities can be leveraged wherever and however they are needed.

# Validation Orchestration and the Iterative Feedback Loop

While discovery and navigation lay the groundwork for successful AI authoring, a robust validation orchestration engine is what ensures the quality and compliance of the final product. The proposed `CHAT_DIRECTOR` moves beyond a simple pass/fail validation model to create an iterative feedback loop, empowering AI-Chat agents to learn from their mistakes and refine their outputs in real-time. This is achieved through a sophisticated system of incremental validation APIs and a standardized correction protocol embedded within diagnostic messages . The architecture allows for fast, partial checks during the drafting phase and provides structured, actionable feedback when

errors are encountered, creating a mechanical, self-correcting workflow that minimizes manual intervention and accelerates the path to a valid artifact [40]. This approach transforms validation from a terminal gatekeeping step into a continuous, guiding process that actively helps the AI succeed.

The validation engine is orchestrated by the `Validator` module, which coordinates checks across four distinct layers: Schema, Invariant, Manifest, and Envelope . This layered approach is the foundation of the incremental validation strategy. The `Validator` provides several key APIs to support different stages of the authoring process. For rapid feedback during drafting, `Validator::quick_schema_check()` performs only the schema validation, which is computationally inexpensive and can be run frequently . As the AI gets closer to a final output, it can escalate to `Validator::validate_up_to()`, which allows validation to proceed up to a specified layer (e.g., stop after checking invariants) . Only when the artifact is nearly complete would a full, four-layer validation be performed using `Validator::validate_all()` . This tiered system significantly reduces the round-trip cost for the AI agent. It can quickly identify structural errors without paying the computational price of evaluating complex invariant interactions or manifest policies until it is ready. This aligns with the principles of efficient tooling, where fast feedback is prioritized to keep the developer (or AI agent) in a productive flow state [34].

When validation fails, the system's true power is revealed in its structured diagnostics. The `ValidationError` and `Diagnostic` structs are not just simple error codes; they are rich objects designed to facilitate automatic correction . A key innovation is the standardization of a "correction-hint protocol" on these diagnostic objects . Each `Diagnostic` now carries a structured suggestion for how to fix the issue, including a `suggestedValue`, a `suggestedRange` for numeric fields, and a short `suggestionText` with imperative wording (e.g., "Reduce the DET value to be less than 1.0") . This is made possible by implementing a `to_correction_hint()` method on each error type, which uses information from the `SpineIndex` and XMIT rules to generate a plausible and contextually appropriate fix . For example, if an AI generates an event with a `DET` value of 12.0, the `InvariantEngine` will produce a diagnostic with a suggested range of `0.0` to `1.0`. The AI agent can then parse this diagnostic, extract the suggested value, apply the patch to its generated JSON, and re-validate the corrected payload—all programmatically, without needing to interpret natural language error messages or rely on bespoke heuristics for each error code [40]. This creates a tight, mechanical feedback loop: read diagnostic -> apply suggested patch -> re-validate.

The validation process itself is meticulously broken down into its constituent parts, with each layer handled by a specialized module. The `validate_schema()` function uses a library like `serde` to check the payload against its corresponding JSON schema [52]. The `validate_invariants()` function, powered by the `InvariantEngine`, extracts invariant and metric values from the payload, applies cross-metric interaction rules (XMIT), and checks all values against their defined ranges, including tier-specific overrides . The `validate_manifests()` function consults the `ManifestIndex` to verify that the target repository and path are valid for the artifact's `objectKind` and `tier` . Finally, `validate_envelope()` ensures the outer `PrismEnvelope` wrapping the payload is correctly formed and that the hash inside matches the computed hash of the payload . The `Validator` orchestrates these steps, collecting all resulting `Diagnostic`s and passing them to the `rank_diagnostics()` function, which sorts them by severity, ensuring that the most critical failures are reported first . The entire validation result is encapsulated in a `ValidationResult` struct, which clearly distinguishes between fatal errors (which halt the process) and warnings (which allow the process to continue) . This granular, layered, and highly structured approach to validation provides the AI-Chat with the precise, actionable information it needs to navigate the complex constraints of the Horror$Place constellation and successfully generate compliant artifacts.

| Validation Layer | Responsible Module | Key Functionality | Typical AI Correction |
|---|---|---|---|
| **Envelope** | `validate/envelope.rs` | Validates the `PrismEnvelope` structure, including the `sessionId` and `hash` computation. | Ensure the payload is wrapped in a valid envelope and the hash is correct. |
| **Schema** | `validate/schema.rs` | Checks the payload's structure and field types against its JSON schema. | Fix missing fields, incorrect data types (e.g., string vs. number), or extra unexpected fields. |
| **Invariant/Metric** | `validate/invariants.rs` | Enforces numeric ranges for invariants and metrics, applying XMIT rules. | Adjust numeric values to fall within the safe bands provided by the spine. |
| **Manifest** | `validate/manifests.rs` | Verifies that the target repo and path are allowed for the `objectKind` and `tier`. | Choose a different `objectKind`, `tier`, or revise the target path to comply with manifest rules. |

This comprehensive validation orchestration is the guardian of the constellation's integrity. It works in concert with the discovery and scaffolding features to create a holistic authoring environment. The AI is first guided to the right place with the right tools (discovery), then given a proper blueprint to work from (scaffolding), and finally, equipped with a detailed instruction manual and a correction tape to fix its mistakes along the way (validation). This iterative, feedback-driven workflow is essential for building a system that is not only correct but also usable and productive for AI-Chat agents operating within the intricate rules of the Horror$Place universe.

# Synthesis and Strategic Implications for AI Authoring

The development of a Rust-based `CHAT_DIRECTOR` as outlined in the research represents a strategic shift towards a more structured, reliable, and scalable paradigm for AI-assisted content creation. By prioritizing foundational infrastructure for discovery and navigation over isolated validation tools, the proposed architecture establishes `CHAT_DIRECTOR` as a central, intelligent orchestration layer rather than a mere compiler or linter. This synthesis of capability catalog, manifest-driven routing, spine-aware indexing, and an iterative validation loop creates a cohesive framework where the AI-Chat operates as a disciplined agent within a tightly defined, machine-readable contract system. The strategic implications of this approach are profound, promising to enhance authoring safety, increase production efficiency, and foster a more consistent and predictable creative process within the Horror$Place constellation.

The core strategic advantage of this framework is its ability to mitigate the inherent risks of generative AI in a complex, rule-governed environment. Traditional approaches often rely on prompt engineering, which is brittle and prone to context drift, or post-hoc validation, which can be too late to salvage a flawed artifact [64] [149]. The `CHAT_DIRECTOR`-based system proactively addresses these issues. The discovery-first philosophy, embodied by the `CapabilityCatalog` and `ManifestIndex`, ensures that the AI's actions are grounded in a verified, real-time map of the constellation's rules and repository structure . This front-loads compliance, preventing a vast class of errors related to schema drift, incorrect artifact placement, and violation of tier-specific policies before any significant generation effort is expended. The structured scaffolding provided by the `SkeletonGenerator`, with its `safe_defaults` and clear field annotations, further reinforces this by constraining the AI's creative freedom within a numerically and structurally valid envelope . This moves the system away from a "garbage in, garbage out" model towards a "guidance-enabled generation" model.

Furthermore, the dual-use architecture, supporting both a powerful offline CLI and a flexible embedded HTTP service, ensures that these benefits are universally accessible . Developers and automated systems can leverage the robust, self-contained CLI for scripting and CI/CD, guaranteeing that all contributions meet the project's standards. Simultaneously, interactive applications and IDE integrations can tap into the low-latency HTTP service to provide real-time, in-context assistance to human authors and AI agents, creating a seamless and responsive authoring experience. This separation of concerns allows the core logic to evolve independently of its interfaces, promoting stability and encouraging adoption across a wide range of use cases. The emphasis on stable, versioned JSON schemas for all APIs, both in the CLI and the HTTP service, is a critical

enabler of this interoperability, ensuring that clients can depend on a consistent interface [1][2][3].

Looking forward, the proposed architecture lays a solid foundation for future evolution and intelligence. The inclusion of a pluggable `TelemetrySink` and the concept of a telemetry-driven learning loop point toward a system that can analyze patterns of AI-generated errors and use that data to improve its own guidance over time . By logging validation outcomes, common error codes, and correction patterns, the `CHAT_DIRECTOR` can begin to build a corpus of "structured failure" that can inform the tuning of the spine's default bands, the refinement of manifest policies, and the enhancement of its correction-hint algorithms [47]. This creates a virtuous cycle of improvement, where the very act of using the system generates data to make the system better for future users. The planned AI-fuzz tests and regression suites will be instrumental in this process, providing a controlled environment to test the system against a wide range of edge cases and ensure that improvements do not introduce new regressions .

In conclusion, the research and proposed implementation of a Rust-based `CHAT_DIRECTOR` provide a comprehensive and principled solution to the challenge of integrating AI-Chat into a large-scale, collaborative game development workflow. By focusing on foundational infrastructure for discovery and navigation, the system successfully transforms the AI from an unpredictable force into a valuable and reliable partner. It replaces ambiguity with contract, guesswork with guidance, and post-facto correction with an iterative feedback loop. The resulting framework not only ensures the immediate safety and quality of generated assets but also establishes a robust, extensible, and intelligent platform for the future of AI-assisted authoring within the Horror$Place constellation.
